

Math 341 Exam 1 - In Class Part
March 19, 2009

Name _____

Show all of your work.

No calculators permitted.

Do not leave any answers blank.

1. (a) For the following differential equation, describe the behavior of y as $t \rightarrow \infty$.

$$\frac{dy}{dt} = 2y - 6$$

- (b) For the following differential equation:

$$y'' - 3y' - 4y = 0$$

Find all possible solutions of the form $y = e^{kx}$.

2. Find the explicit solution to the following initial value problem.

$$\frac{dy}{dx} = e^{-y} \cos x, \quad y(0) = 2$$

3. Find the appropriate integrating factor for the given differential equation that would allow you to solve (at least implicitly) the differential equation using the techniques of this class. **You do not need to solve the equation, only find the integrating factor!**

(a) $\frac{dy}{dt} + 10ty = t + 3$

(b) $(3x + 4) \sin y + 4x \cos y \frac{dy}{dx}$

4. Find the general (implicit) solution to the following exact differential equation.

$$6xy^5 - 1 + (15x^2y^4 + 2) \frac{dy}{dx} = 0$$

5. Consider the following autonomous differential equation:

$$\frac{dy}{dt} = (y - 1)^2 (y - 3) = y^3 - 5y^2 + 7y - 3 = f(y)$$

- (a) Sketch the graph of $f(y)$ versus y and indicate all relevant information.
- (b) Sketch several graphs of solutions in the ty -plane (for $t \geq 0$), making sure to include enough detail so that
- i. No type of solution is omitted.
 - ii. The stability of all equilibrium solutions can be visually determined.
 - iii. The shape of each solution is clear.
 - iv. The location of any inflection points is clear.

6. Suppose that a tank holds 500 liters of a saltwater solution containing 30 grams of salt. At time $t = 0$, a pump system is turned on that allows a saltwater solution with 2 grams of salt per liter to flow into the tank at a rate of 4 liters per minute. The system also causes the solution in the tank to flow out at the same rate. Create, **but do not solve**, an initial value problem to model this situation.

7. (a) Let $y = \phi(t)$ be the solution to the initial value problem below. Use one step, with stepsize 0.1, of Euler's Method to approximate $\phi(0.1)$

$$\frac{dy}{dt} = (t^2 - 2)(y^2 + t), y(0) = 3.$$

(b) Consider the following 3 differential equations.

$$\text{DE 1: } \frac{d^2y}{dt^2} - \frac{3}{y} = 5t$$

$$\text{DE 2: } \frac{dy}{dt} = t^2y^2$$

$$\text{DE 3: } \frac{d^2y}{dt^2} = t^3 \frac{dy}{dt} - (t + 4)y + 1$$

i. Which of these are linear?

ii. Which of these are second-order?
